## Introduction

## Using the Score Fusion App

#### 2.1 Quick Start

- 2.1.1 Executable Download
- 2.1.2 Download from Source (GitHub)

#### 2.2 Input Files

This application performs analysis of provided scores. Because analysis and this application's performance relies upon correctly interpreting the data provided, it is very important to understand the file formats the application can understand.

#### Things that are true, regardless of input file format:

- Subject IDs: The application does its best to identify what might be a subject id. IF IDs are strictly numeric, that makes detection more challenging. If Subject IDs are included as column or row headers, ensure they are not strictly numeric.
- Test / Train detection: The application checks filenames for "test" and "train" to determine if the data is already split into training and testing samples. Please be sure to have train and test anywhere in the filename where appropriate.

#### 2.2.1 Matrix Form

This score format contains subjects along the rows and columns such that genuine scores are along the diagonal, and the impostor scores are off diagonal.

#### Good things to know:

- labels are not necessary, scores along the diagonal are *genuine*, off diagonal scores are *impostor*
- Each modality should be its own file. That file name will be what the modality is referred to as in the application.

A pictorial example of this format for the NIST Biometric Score Dataset (Face x Finger) at NIST BSSR1, with subject IDs as row and column headers.

Figure 2.1: Score Matrix with Headers.

#### **Assumptions:**

- The order of subjects is consistent along the column and rows
- There are the same number of rows and columns
- IF there are row or column headers identifying the subject id, that id is not in the same format as the scores (i.e. subject ids should not be floats or pure integers)

#### 2.2.2 Column Form

Column formatted data are assumed to be represented as a collection of columns, which contain at least:

- Subject ID
- Gallery ID
- Score Column(s)

#### N: M Score Data

If there are more than 1:N scores for subject to gallery ids, please ensure that the score data is formatted such that the following column headers exist:

- probe subject id
- probe file id
- candidate subject id
- candidate file id
- genuine flag

#### Important things to know:

This format is based along the concept that there are modalities along the columns, with the last column containing the label(0 impostor, 1 genuine) OR the first 2 columns must be subject ids - in which case, genuine impostor labels may be determined by checking if the first two column ids are equal (genuine) or not (imposter).

- Each column must have a header. This is how the application knows modality titles.
- The label for this last column should be titled label or class (capitalization does not matter)

#### 2.3 Train and Test Splitting

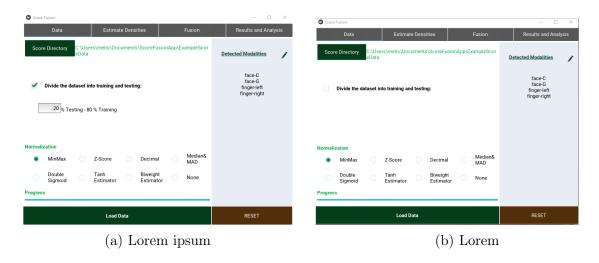

Figure 2.2: Caption place holder

#### 2.4 Normalization

Normalization puts all the scores into a common domain. Consider a matcher's whose scores are between -1 and 1, while another matcher's scores are between 100 and 500. In order to fuse the scores from these two matchers, the scores must be normalized into a common range.

The following are the normalization techniques supported by the Score Fusion App.

#### 2.4.1 MinMax

MinMax normalization scales score values between 0 and 1, and it is a common normalization approach. This is the Score Fusion App's default normalization. MinMax normalization is sensitive to outliers.

$$s' = \frac{s - M_{min}}{M_{max} - M_{min}} \tag{2.1}$$

#### 2.4.2 **Z-Score**

Z-Score normalization is more robust to outliers by using scores' means  $(\mu)$  and standard deviations  $(\sigma)$ . Note that if the unnormalized data has a large standard deviation, the

normalized score values will be near 0.

$$s' = \frac{s - M_{\mu}}{M_{\sigma}} \tag{2.2}$$

#### 2.4.3 Decimal

Decimal scaling puts scores into the range of 0 to 1. For instance, consider scores in the range 100 to 9,000. These are scaled to the range 0.01 to 0.9 by dividing score s by  $10^4$ . Equation 2.3 formally defines decimal scaling. In the above example, j=4, as the largest score value is 9,000 ( $10^4$ ).

$$s' = \frac{s}{10^j} \tag{2.3}$$

#### 2.4.4 Median & MAD

$$s' = \frac{s - median(s)}{MAD(s)} \tag{2.4}$$

#### 2.4.5 Double Sigmoid

$$s' = \begin{cases} 1/(1 + (exp(-2((s-t)/r_1))), & \text{if s < t} \\ 1/(1 + (exp(-2((s-t)/r_2))), & \text{if s \ge t} \end{cases}$$
 (2.5)

#### 2.4.6 Tanh Estimator

$$s' = \frac{s - median(s)}{MAD(s)} \tag{2.6}$$

#### 2.4.7 Biweight Estimator

#### 2.4.8 None

You can choose to not normalize the scores to a common domain. This option is not recommended unless you are certain that all modalities already are in a consistent range.

$$s' = s \tag{2.7}$$

### 2.5 Editing Detected Modalities

Modalities are automatically detected by either the file names or column headers, and by default are set as similarity scores. Users can edit these by clicking on the pencil icon next to the "Detected Modalities" pane. This will bring up the "Edit Modalities" popup as seen in Figure 2.3.

This popup allows users to change the names of the modalities, select a subsection of available modalities for fusion, and specify if a modality's scores are dissimilarity scores. Note, the Update button must be clicked for these changes to take effect.

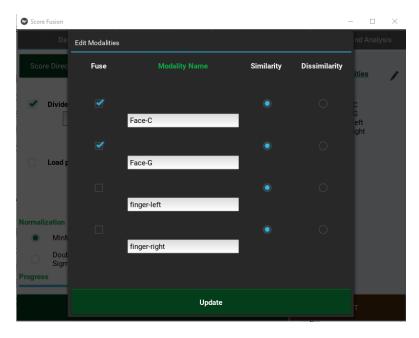

Figure 2.3: Edit detected modalities screen.

## 2.6 Density Estimates

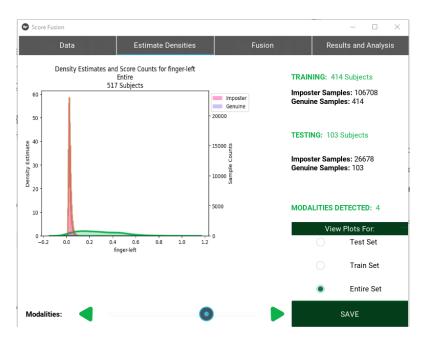

Figure 2.4: Estimate Densities tab, which features score distribution plots and test/train metrics for modalities.

#### 2.7 Fusion

### 2.8.2 Experiment Slider

## Advanced

#### 3.1 Internal Score Data Structure

No matter how the input files are structured, this app creates a consistent score matrix representation to be used throughout interactions with the application. This score matrix dataframe contains the following columns: Train\_Test category, Probe\_ID, Gallery\_ID, Label, Original Scores (multiple columns), Normalized Scores (multiple columns), and Fused Scores (one or more multiple columns).

For Example, Figure 3.1 is a screenshot of the internal score matrix generated for the NIST BSSR1 multimodal dataset.

Figure 3.1: Screenshot of internal Score matrix derived from the NIST BSSR1 dataset.
